The Erdös Number

The Erdös Number:

Through how many research collaboration links is an arbitrary scientist connected to Paul Erdös?

What is a research collaboration link?

Per definition: Co-authorship on a scientific paper -> Convenient: Amenable to computational analysis

What is my Erdös Number?

→ 5

me -> S. Easterbrook -> A. Finkelstein -> D. Gabbay -> S. Shelah -> P. Erdös

Stanley Milgram

- · A social psychologist
- · Yale and Harvard University
- Study on the Small World Problem, beyond well defined communities and relations (such as actors, scientists, ...)

1933-1984

- Controversial: The Obedience Study
- What we will discuss today: "An Experimental Study of the Small World Problem"

Markus Strohmaier

2008

Introduction

The simplest way of formulating the small-world problem is: Starting with any two people in the world, what is the likelihood that they will know each other?

A somewhat more sophisticated formulation, however, takes account of the fact that while person X and Z may not know each other directly, they may share a mutual acquaintance - that is, a person who knows both of them. One can then think of an acquaintance chain with X knowing Y and Y knowing Z. Moreover, one can imagine circumstances in which X is linked to Z not by a single link, but by a series of links, X-A-B-C-D...Y-Z. That is to say, person X knows person A who in turn knows person B, who knows C... who knows Y, who knows Z.

[Milgram 1967, according to]http://www.ils.unc.edu/dpr/port/socialnetworking/theory_paper.html#2]

An Experimental Study of the Small World Problem [Travers and Milgram 1969]

A Social Network Experiment tailored towards

- Demonstrating
- Defining
- And measuring

Inter-connectedness in a large society (USA)

A test of the modern idea of "six degrees of separation" Which states that: every person on earth is connected to any other person through a chain of acquaintances not longer than 6

Markus Strohmaier

2008

Experiment

Goal

- Define a single target person and a group of starting persons
- · Generate an acquaintance chain from each starter to the target

Experimental Set Up

- · Each starter receives a document
- was asked to begin moving it by mail toward the target
- Information about the target: name, address, occupation, company, college, year of graduation, wife's name and hometown
- Information about relationship (friend/acquaintance) [Granovetter 1973]

Constraints

- starter group was only allowed to send the document to people they know and
- was urged to choose the next recipient in a way as to advance the progress of the document toward the target

Markus Strohmaier

2008

11

Knowledge Management Institut

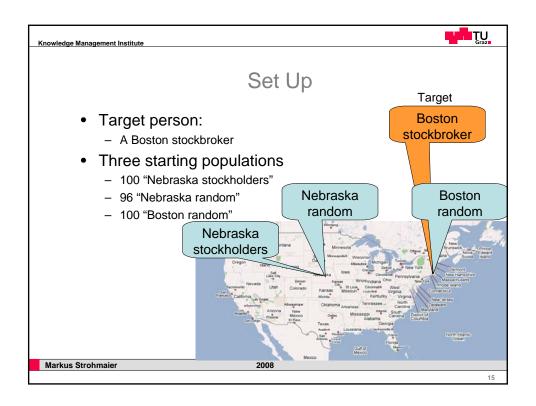

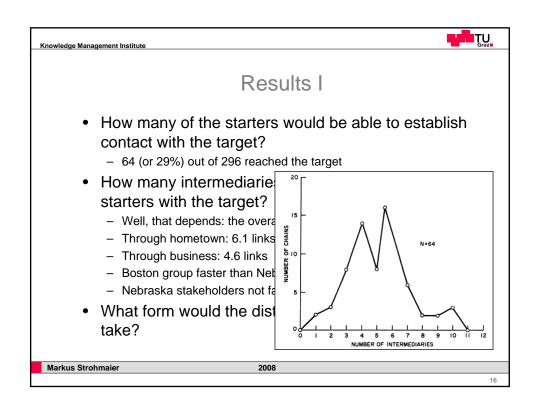

Questions

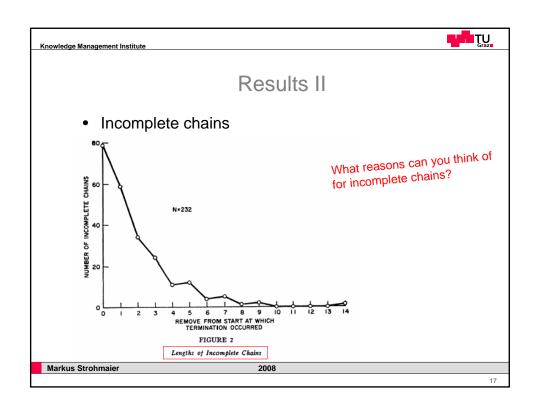

- How many of the starters would be able to establish contact with the target?
- How many intermediaries would be required to link starters with the target?
- What form would the distribution of chain lengths take?

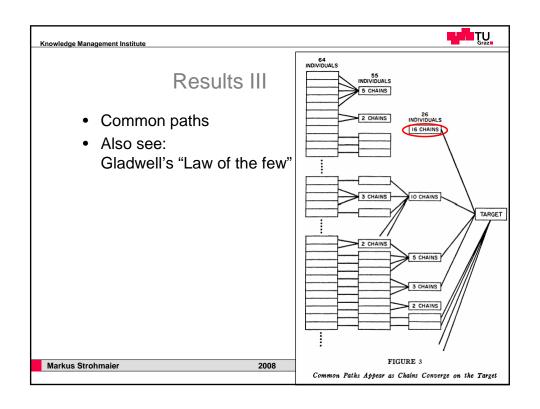

Markus Strohmaier

2008

6 degrees of separation

 So is there an upper bound of six degrees of separation in social networks?

What kind of problems do you see with the results of this study?

- Extremely hard to test
- In Milgram's study, ~2/3 of the chains didn't reach the target
- 1/3 random, 1/3 blue chip owners, 1/3 from Boston
- Danger of loops (mitigated in Milgram's study through chain records)
- Target had a "high social status" [Kleinfeld 2000]

Small Worlds

http://www.infosci.cornell.edu/courses/info204/2007sp/

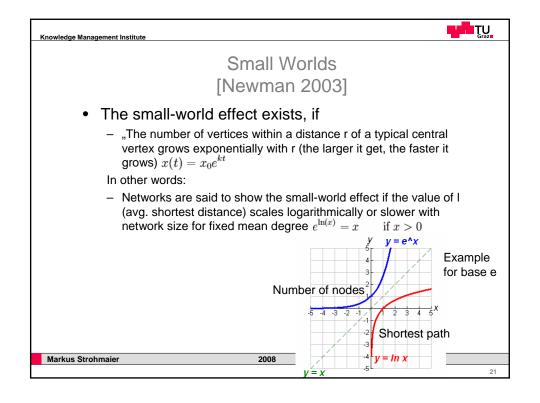

- Every pair of nodes in a graph is connected by a path with an extremely small number of steps (low diameter)
- Two principle ways of encountering small worlds
 - Dense networks
 - sparse networks with well-placed connectors

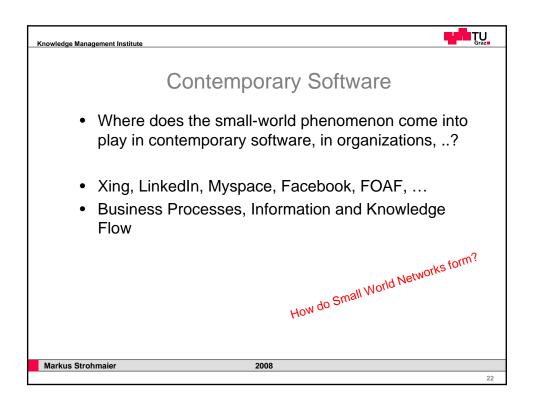

Markus Strohmaier

2008

Preferential Attachment [Barabasi 1999]

"The rich getting richer"

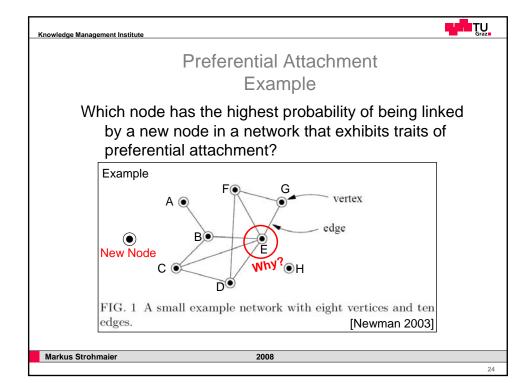

Preferential Attachment refers to the high probability of a new vertex to connect to a vertex that already has a large number of connections

Example:

- 1. a new website linking to more established ones
- 2. a new individual linking to well-known individuals in a social network

Markus Strohmaier

2008

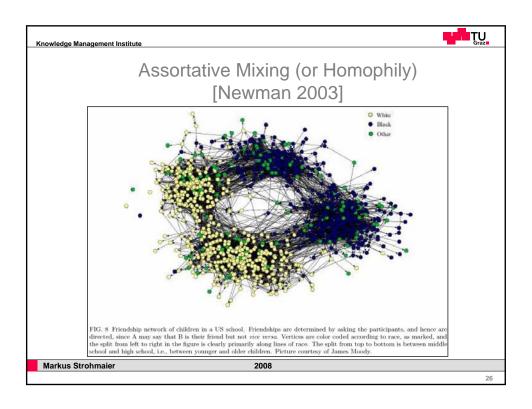

Assortative Mixing (or Homophily) [Newman 2003]

Assortative Mixing refers to selective linking of nodes to other nodes who share some common property

- E.g. degree correlation high degree nodes in a network associate preferentially with other high-degree nodes
- E.g. social networks nodes of a certain type tend to associate with the same type of nodes (e.g. by race)

Markus Strohmaier

2008

Disassortativity [Newman 2003]

Disassortativity refers to selective linking of nodes to other nodes who are different in some property

 E.g. the web low degree nodes tend to associate with high degree nodes

Markus Strohmaier

2008

Network Resilience [Newman 2003]

The resilience of networks with respect to vertex removal and network connectivity.

If vertices are removed from a network, the typical length of paths between pairs of vertices will increase – vertex pairs will be disconnected.

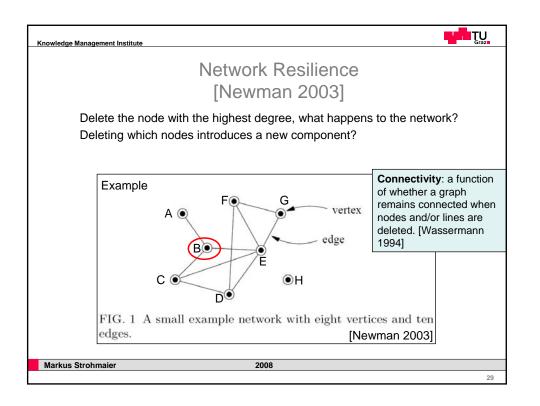

Examples:

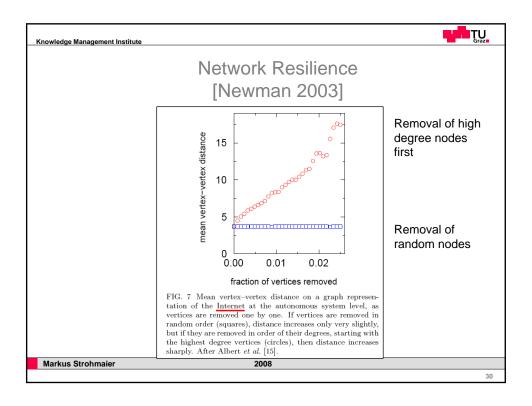

- 1. Deletion of a hub
- 2. Deletion of a leaf node element

The web is highly resilient against random failure of vertices, but highly vulnerable to deliberate attack on its highest-degree vertices

Markus Strohmaier

2008

Connectivity of the Web [Newman 2003, Broder et al 2000]

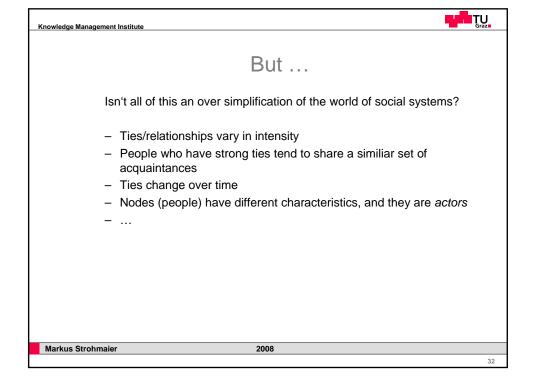

What does it need to destroy the connectivity of the web?

According to Broder et al 2000, you need to remove all vertices with a degree greater than five.

Because of the highly skewed degree distribution of the web, the fraction of vertices with degree greater than five is only a small fraction of all vertices.

The Strength of Weak Ties [Granovetter 1973]

The strength of an interpersonal tie is a

- (probably linear) combination of the amount of time
- The emotional intensity
- The intimacy
- The reciprocal services which characterize the tie

Mark Granovetter, Stanford University

Can you give examples of strong / weak ties?

Markus Strohmaier

The Strength of Weak Ties and Mutual Acquaintances [Granovetter 1973]

Consider:

Two arbitrarily selected individuals A and B and The set S = C,D,E of all persons with ties to either or both of them

Hypothesis:

The stronger the tie between A and B, the larger the proportion of individuals in S to whom they will both be tied.

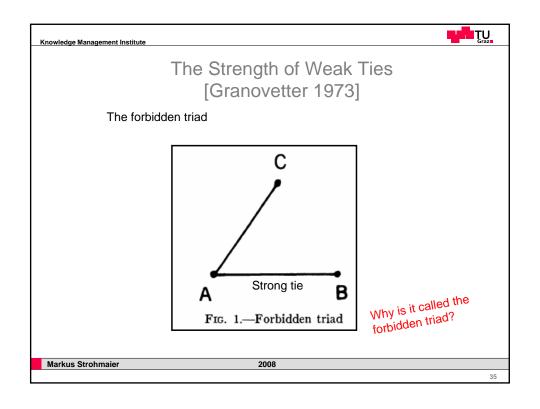

Theoretical corroboration:

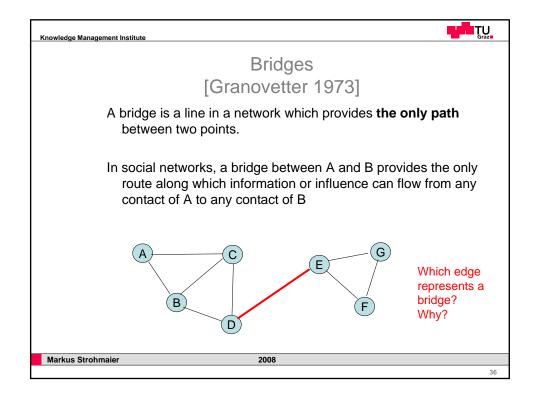

Stronger ties involve larger time commitments – probability of B meeting with some friend of A (who B does not know yet) is increased

The stronger a tie connecting two individuals, the more similar they are

Markus Strohmaier

2008

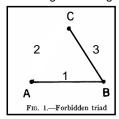

Bridges and Strong Ties [Granovetter 1973]

Example:

- 1. Imagine the strong tie between A and B
- 2. Imagine the strong tie between B and C
- 3. Then, the forbidden triad **implies** that a tie **exists** between C and B (it forbids that a tie between C and B does not exist)
- From that follows, that A-B is not a bridge (because there is another path A-B that goes through C)

Why is this interesting?

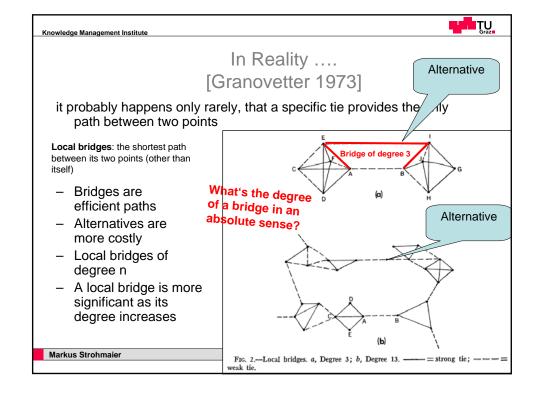

- ⇒Strong ties can be a bridge ONLY IF neither party to it has any other strong ties
- ⇒Highly unlikely in a social network of any size
- ⇒Weak ties suffer no such restriction, though they are not automatically bridges
- ⇒But, all bridges are weak ties

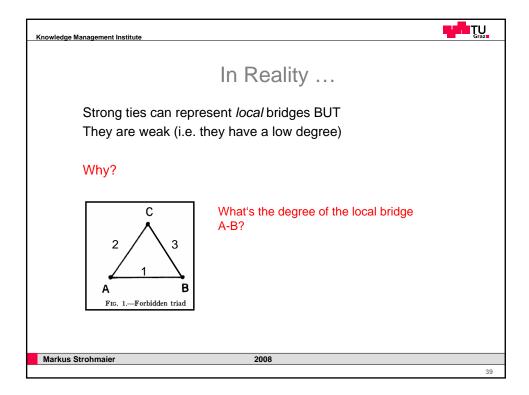

Markus Strohmaier

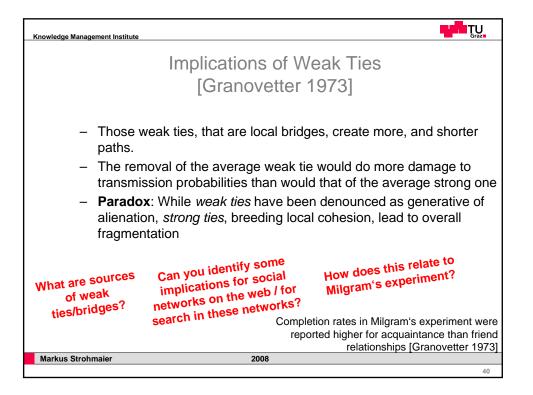

2008

37

ŢŲ

Implications of Weak Ties [Granovetter 1973]

- Example: Spread of information/rumors in social networks
 - Studies have shown that people rarely act on mass-media information unless it is also transmitted through personal ties [Granovetter 2003, p 1274]
 - Information/rumors moving through strong ties is much more likely to be limited to a few cliques than that going via weak ones, bridges will not be crossed

How does information spread through weak ties?

Markus Strohmaier
